Governance Security and Transparency Pilot

A four-week demonstration proposal for document-grounded AI assistance and read-only CyberChain verification.

Document reference	CG-DEMO-2026-01 / version 1.0
Prepared	26 October 2026
DAO ID	cyber-demo-dao
Proposal type	STANDARD
Proposal title	CyberGovAI Governance Security and Transparency Pilot
Decision requested	Approve the proposed pilot and its EUR 12,000 budget.

1. Purpose and agenda

Approve a four-week pilot to improve governance transparency, verify proposal and voting records against CyberChain, and evaluate evidence-based AI assistance.

The agenda has three parts: independently review governance security, improve visibility of proposal and voting records, and assess whether AI answers are supported by the linked proposal PDF and actual blockchain reads.

2. Proposed scope

The security review covers proposal creation, member assignment, vote recording, result finalization, wallet authentication and access control. The transparency dashboard presents proposal status, recorded votes, transaction references and database-to-chain discrepancies. The AI assistant summarizes linked documents, cites supporting excerpts and separates unavailable facts from observed facts.

Demonstration status

This document is synthetic test data. It is not a real auditor quotation, an approved budget or evidence of completed work. Approval does not automatically transfer funds or execute contract changes. A separate authorized process is required for any payment or implementation.

3. Proposed budget

Work package	Amount	Allocation
Independent security review	EUR 6,000	50%
Governance dashboard improvements	EUR 3,000	25%
AI evaluation and evidence checks	EUR 2,000	16.67%
Contingency	EUR 1,000	8.33%
Total proposed budget	EUR 12,000	100%

Contingency is reserved for unexpected testing or remediation effort. It must not be treated as already spent. No supplier has been appointed and no payment recipient is specified.

4. Delivery schedule

Day 1 means the pilot kickoff after approval and confirmation of an implementation owner. These delivery milestones are separate from the on-chain voting start and end times.

Deadline	Deliverable	Acceptance condition
Day 7	Inventory and review plan	Document the governance components and test cases.
Day 14	Security findings report	Classify findings by severity and propose remediation.
Day 21	Dashboard and AI evaluation dataset	Show governance records and evaluate at least 20 labeled questions.
Day 28	Final pilot report	Publish measured results, limitations and unresolved issues.

5. Success criteria

Every factual AI answer must cite the supporting document excerpt or structured governance evidence. Unsupported questions must be answered without fabricated facts. On-chain checks must record the actual chain ID, contract address and pinned block number. Multi-question requests must preserve question order and show separate results. Conversation history must reopen without requiring a second wallet connection when the wallet is already connected.

Evaluation should report routing, citation checks, tool outcomes, latency and model-reported token usage. Missing measurements must remain unknown. No numerical accuracy threshold or claim of achieved performance is established by this proposal.

6. Risks and mitigations

Risk	Planned mitigation
Unsupported or misleading AI answers	Use evidence citations, abstention for missing facts and human review.
RPC outage or a changing blockchain snapshot	Use bounded read requests and a pinned block; report unavailable or unverified results.
Differences between database and blockchain	Display both values, provenance and the specific discrepancy; do not silently overwrite records.
Private credentials reaching the browser	Keep operator tokens and database credentials server-side; reuse authenticated backend authorization.
PDF text unavailable to retrieval	Check document linkage, SHA-256 verification and a compatible text/embedding index.
Budget or delivery overrun	Review milestones weekly and require explicit approval for scope changes.

7. Governance and voting

The proposed voting options are Approve, Reject and Abstain. Actual eligibility, assigned members, vote totals, quorum and final result are governed by the deployed contract and live application state. This PDF does not establish a quorum percentage or claim an outcome.

For the demonstration, configure voting dates and assign test-wallet addresses in the UI. Assignment counts and votes must be queried from the application or chain after creation. The document intentionally contains no invented proposal ID, contract address, transaction hash, block number or current vote tally.

8. Evidence boundaries

This PDF supports questions about the proposed purpose, scope, budget, schedule, deliverables, risks and success criteria. It does not prove that a security audit has been completed, that funds were released, that a supplier was selected or that any proposal was approved. It does not identify a secret password or API credentials.

Document linkage and hash verification establish which bytes were attached to the proposal. They do not establish that the proposal claims are true or that the described work has happened. Live governance facts require independent database or blockchain reads.
